Tiling deficient rectangles with trominoes

J. Marshall Ash and Solomon W. Golomb

Introduction

A tromino (rhymes with domino) is a shape made up of three 1 \times 1 squares assembled as shown.

![Figure 1. A tromino](image)

We will classify a variety of nearly rectangular shapes into those which can be tiled by trominoes and those which cannot. From now on we will simply say tiled to mean tiled by trominoes. We will consider shapes that are integer-dimensioned rectangles with each dimension at least 2, and with one or two 1 \times 1 squares removed. If one square is removed, call the resultant shape a deficient rectangle. If the removed square was a corner square, call the resulting deficient rectangle a dog-eared rectangle. If two squares are removed, call the resultant shape a 2-deficient rectangle. The area of a tromino is 3, so only shapes whose area is a multiple of 3 can be tiled by trominoes. In this paper we will determine which deficient rectangles with area divisible by 3 are tileable and which are not; in particular, all the dog-eared ones are tileable. We will also get some partial results for the same question for 2-deficient rectangles with area divisible by 3.

The proof the Deficient 5 \times 5 Lemma is especially recommended to the casual reader.

Trominoes were introduced in [G] where Golomb proved that deficient squares whose side length is a power of two can be tiled. Chu and Johnsonbaugh first extended Golomb's work to the cases of deficient squares in general. [CJ] They later went on to rectangles and proved a slightly weaker version of what we call

This paper is in final form and no version of it will be submitted for publication elsewhere.
below the De...cient Rectangle Theorem.[CJ 1]. The Proposition in the last section answers a question that they posed in [CJ ].

Before proceeding with the business at hand, we will mention a few general facts about trominoes and about other tiling question involving tiles other than trominoes.

A tromino is a special case of a polyomino, a shape made by connecting certain numbers of 1 £ 1 squares, each joined together with at least one other square along an edge. The polyomino of area 1, a single 1 £ 1 tile is called a monomino. The polyomino of area two is the domino. Let \( P(n) \) be the number of distinct polyominoes of area \( n \). For example \( P(3) = 2 \), since there are actually two trominoes, a straight tromino, which has the shape of a 1 £ 3 rectangle; and the object shown in Figure 1 which is called a right tromino when the distinction needs to be made, but which will be the only kind of tromino discussed in this paper. There are both results and open questions in connection with the exponentially growing values of \( P(n) \).[G 1, Appendix D]

Four trominoes can be set together to form a tromino-shaped 4-reptile, that is, a set in the plane which can be tiled by four congruent scaled down copies of itself. A tromino has order 2, which means that the minimum number of trominoes required to form a rectangle is 2.(See Figure 2.) Finding the order of other polyominoes provides challenging problems.[G 1, Chapter 8] The entire plane can be tiled in a periodic way by any polyomino of finite order by simply repeating copies of the minimal rectangle. Roger Penrose has given a remarkably simple aperiodic tiling of the entire plane using copies of only two unit-edged rhombi, one with acute angle 36° and the other with acute angle 72°.[P ] Tilings are often found in Moorish architecture; some trominoes can be seen in a display case in the Reales Alcazares, a great Arabian style palace built during various epochs in Seville, Spain. A comprehensive and interesting book concerning tiling is Tilings and Patterns.[G 5] There is lot of information about tiling available on the internet, look for example at http://www.ics.uci.edu/~eppstein/junkyard/polyomino.html.

Dog-eared rectangles and de...cient rectangles

A basic tiling result that we will need is the full classification of rectangles with area divisible by 3. Let's start with some simple cases. First of all, a 2 £ 3 rectangles can be tiled by trominoes.

Figure 2. Tiling \( R(2, 3) \)

Denote an \( i \) row and \( j \) column rectangle by \( R(i, j) \). We will indicate decompositions into nonoverlapping subrectangles by means of an additive notation. For example, a 3i £ 2j rectangle can be decomposed into \( ij \) 3 £ 2 subrectangles and we write this fact as \( R(3i, 2j) = \sum_{\mu=1}^{i} \sum_{\nu=1}^{j} R(3, 2) = ij R(3, 2) \). It follows from this and the
tiling in Figure 2 that

\[(0.1) \text{ any } 3i \leq 2j \text{ or } 2i \leq 3j \text{ rectangle can be tiled.} \]

From now on, any rectangle decomposed into a combination of \(3i \leq 2j\) subrectangles, \(2i \leq 3j\) subrectangles and trominoes will be considered as successfully tiled by trominoes. Denote the \(1 \times 1\) square lying in row \(i\) and column \(j\) as \((i, j)\).

Now let’s look at some rectangles that cannot be tiled. Suppose that a \(3 \times 3\) square \(Q\) has been tiled. Some tromino must cover square \((3, 1)\). Here are the three possible ways that it can do that.

![Figure 3. An impossibility proof](image)

Orientation \(A\) is immediately ruled out, since square \((1, 1)\) cannot be tiled. But in cases \(B\) and \(C\), the tiling must tile the leftmost \(3 \times 2\) subrectangle of \(Q\), so that the original tiling is also a tiling of the third column of \(Q\), which is an \(R(3, 1)\). This is impossible. Similarly, suppose that a \(3 \times 5\) rectangle \(R\) has been tiled. This argument shows that the tiling must tile the first two columns of \(R\), and hence also the rightmost three columns of \(R\). This is a contradiction since we have just shown \(3 \times 3\) square to be untileable. Iterating this procedure shows no \(R(3, \text{odd})\) can be tiled. It turns out that there are no other untileable rectangle with area divisible by \(3\).

The integers \(m\) and \(n\) will always be greater than or equal to \(2\).

Chu-Johnsonbaugh Theorem.\([\text{CJ}1]\) An \(m \times n\) rectangle can always be tiled by trominoes if \(3\) divides its area \(mn\), except when one dimension is \(3\) and the other is odd.

The proof of this is not hard. We suggest that the reader give it a try. Here are a few hints. Use fact \((0.1)\) several times. First do the cases \(R(3k, \text{even})\); then do the cases \(R(6k, \text{odd})\). This leaves only the cases \(R(9 + 6k, n)\), where \(n \geq 5\) is an odd integer. Reduce such a case to \(R(9, 5)\). Finally tile \(R(9, 5)\) by trial and error. If you have trouble with the last step, look at the top picture in Figure 9 below.

An \(m \times n\) dog-eared rectangle is an \(m \times n\) rectangle with a \(1 \times 1\) corner square removed. We will denote the dog-eared rectangle by \(R(m, n)^\dagger\), so that \(R(m, n)^\dagger = \)
Note that the area of $R(m, n)$ is $mn \pm 1$.

**Dog-eared Rectangle Theorem.** A $m \times n$ dog-eared rectangle can be tiled with trominoes if and only if 3 divides its area.

To understand what this theorem means, note that if $mn$ is congruent to 0 or 2 modulo 3, then the area of $R(m, n)$ is not congruent to 0 modulo 3 and so that dog-eared rectangle cannot be tiled by trominoes, since the area of any region tiled by trominoes must be an integral multiple of 3. So the only $m \times n$ dog-eared rectangles that could possibly be tiled by trominoes are those for which $mn$ is congruent to 1. In other words, the only $m \times n$ dog-eared rectangles that could possibly be tiled by trominoes are those for which $m \not\equiv n \not\equiv 1$ (mod 3) or $m \not\equiv n \not\equiv 2$ (mod 3), and, indeed, all those dog-eared rectangles can be tiled.

We start with a family of special cases of the Dog-eared Rectangle Theorem, the dog-eared dyadic squares, $R(2^k, 2^k)$. This is a special case of a well known beautiful example of mathematical induction. (See [G], [G1], page 4, [J1], page 45, or problem 2.3.38 of [Z]). If $k = 1$, note that $R(2, 2)$ is itself a tromino. If $k = 2$, see Figure 5 for a covering of $R(4, 4)$.

In Figure 5, $R(4, 4)$ was tiled by dividing it into 4 quadrants. The upper right quadrant is an $R(2, 2)$ while the other three quadrants were all congruent to $R(2, 2)$. Then the black tromino covering squares $(2, 2), (2, 3)$, and $(3, 3)$ was placed at the center. This reduced the lower left quadrant to an $R(2, 2)$ and the remaining two quadrants to rotations of $R(2, 2)$. In short, the tiling of $R(4, 4)$ was reduced...
TILING WITH TROMINOS

The reader should next do $k = 3$, by dividing $R(8, 8)^i$ into 4 quadrants, and then covering the central squares $(4, 4)$, $(4, 5)$, and $(5, 5)$ with a tromino. This reduces the tiling of $R(8, 8)^i$ to the tiling of four copies of $R(4, 4)^i$. The general inductive proof should now be clear.

Proof of the Dog-eared Rectangle Theorem. Let $m \cdot n$. As mentioned above, the necessary condition that $3$ divide the area of $R^i = R(m, n)^i$ splits into the cases $m \not\equiv n \not\equiv 1$ (mod 3) and $m \not\equiv n \not\equiv 2$ (mod 3). It is not hard to see that the $m \leq n$ dog-eared rectangle is congruent to the $n \leq m$ one. So, in the former case, we have either $R(4, 3k + 4)^i$ with $k \geq 0$, $R(7, 6k + 7)^i$ with $k = 0$, $R(7, 6k + 4)^i$ with $k = 1$, or $R(3j + 4, 3k + 4)^i$ with $j \geq 2$ and $k \geq 2$. There correspond these four decompositions.

$$R(4, 3k + 4)^i = R(4, 3k) + R(4, 4)^i, k \geq 0$$

$$R(7, 6k + 7)^i = R(7, 6k) + R(7, 7)^i, k \geq 0$$

$$R(7, 6k + 4)^i = R(7, 6k) + R(4, 3) + R(4, 4)^i, k \geq 1$$

$$R(3j + 4, 3k + 4)^i = R(3j, 3k + 4) + R(4, 3k) + R(4, 4)^i, j, k \geq 2.$$  

For the algebraically inclined reader, these decompositions need no further explanation. However, the geometrically inclined reader should draw pictures to visualize them. (All the similar decompositions appearing below have straightforward geometrical interpretations.) Here, in the first three cases, a large rectangle was stripped from the left side of the figure. In the fourth case, first a large rectangle was removed from the bottom, and then another from the left side of what remained. All the full rectangles are tileable by the Chu-Johnsonbaugh Theorem, $R(4, 4)^i$ is tiled as in Figure 5, and the tiling of $R(7, 7)^i$ appears in [CJ].

In the latter case, we must tile $R^i = R(3j + 2, 3k + 2)^i$ where $0 \leq j \leq k$. If $j \neq 1$, we have

$$R^i = R(3j, 3k) + R(3j, 2) + R(2, 3k) + R(2, 2)^i.$$  

The first three terms are tiled by the Chu-Johnsonbaugh Theorem, while the last term actually is a tromino. Let $j = 1$. Either $k$ is odd, $3k + 2 = 6l + 5$; or else $k$ is even, $3k + 2 = 6l + 8$. Correspondingly, either $R^i = R(5, 6l + 5)^i = R(5, 6l) + R(5, 5)^i$ where the first term is tiled with the Chu-Johnsonbaugh Theorem and $R(5, 5)^i$ is tiled like this.

Figure 6. Tiling $R(5, 5)^i$
or else \( R_i = R(5, 6e + 8t) \) where again the \( t \)st term is tiled with the Chu-Johnsonbaugh Theorem and we also have \( R(5, 8) = R(5, 6) + R(3, 2) + R(2, 2) \), the \( t \)st two terms being tiled by the Chu-Johnsonbaugh Theorem, while the last term is a tromino.

Here is an application of the Chu-Johnsonbaugh and Dog-eared Rectangle Theorems. Consider the practical question of tiling as much as possible of any \( m \times n \) rectangle, where \( m \) and \( n \) both exceed 3. There are 3 cases depending on the value of \( mn \) modulo 3. If \( mn \not\equiv 0 \pmod{3} \), tile the entire rectangle with the Chu-Johnsonbaugh Theorem. If \( mn \equiv 1 \pmod{3} \), remove a single corner tile and then use the Dog-eared Rectangle Theorem to tile the rest of the rectangle. If \( mn \equiv 2 \pmod{3} \), we must remove 2 tiles. It turns out that if \( mn \equiv 2 \pmod{3} \) and if a corner tile and a boundary tile adjacent to it are both removed, what remains can always be tiled. This can be proved by methods very similar to those used to prove the other two theorems. We will leave its proof as an exercise.

Call a rectangle with one \( 1 \times 1 \) square missing a deficient rectangle. Thus to the rectangle \( R(m, n) \) correspond \( mn \) deficient rectangles, each being formed by removing one square from \( R(m, n) \); exactly 4 of these are congruent to \( R(m, n) \). The question of whether a deficient rectangle can be tiled with trominoes is clearly equivalent to the question of whether the full rectangle consisting of the disjoint union of the deficient rectangle and the \( 1 \times 1 \) square can be tiled by a set of trominoes and a single monomino, with the monomino covering the missing square.

Say that a \( 1 \times 1 \) square is good if its removal from a full \( m \times n \) rectangle produces a deficient rectangle that can be tiled. We will now enumerate all deficient rectangles that cannot be tiled. Let \( R \) be a deficient \( m \times n \) rectangle which cannot be tiled even though 3 divides \( mn \). If \( m = n = 5 \), there are 9 good and 16 bad squares. If \( m = 5 \) and \( n = 5 + 3k \), then there are only 2 bad squares, namely \((3, 2)\) and its reflection \((3, 4 + 3k)\). If \( m = 2 \) and \( n = 2 + 3k \), then exactly the squares \((1, 3j)\) and \((2, 3j)\), \( j = 1, 2, 3 \), are bad.

The case of \((m, n) = (5, 5)\) is certainly the most interesting.

Deficient 5 \( \times \) 5 Lemma. If the square \((i, j)\) is removed from the 5 \( \times \) 5 rectangles where either \( i \) or \( j \) is even, then the resulting shape is not tileable.

Proof. Form a kind of checkerboard design by marking each of the nine squares

\[
\begin{array}{ccc}
& 8 & 9 \\
1 & (1, 1), & (1, 3), & (1, 5), \\
3 & (1, 3), & (3, 3), & (3, 5), \\
& (5, 1), & (5, 3), & (5, 5),
\end{array}
\]

and assume that one of the 16 unmarked squares has been removed from \( R(5, 5) \) to form \( R^i \). Then a proposed tiling of \( R^i \) must contain one tromino for each of the 9 marked squares, so that tiling must have area at least \( 9 \times 3 = 27 \), which is absurd since the area of \( R^i \) is 24. Thus all 16 of the unmarked squares are bad.

Next we note that bad squares can also occur when \((m, n) = (2, 5 + 3k)\), \( k = 0, 1, 2, \ldots \). Here the bad squares are exactly those of the form \((x, 3j)\), \( j = 1, 2, \ldots, k + 1 \). By symmetry we may assume that \( x = 1 \). To show that \( R(2, 5 + 3k) \) cannot be tiled, assume the opposite and let \( T \) be the tromino covering the square \((2, 3j)\). Then to the left of \( T + f(1, 3j) \) lies either the rectangle \( R(2, 3j + 1) \) or the rectangle \( R(2, 3j + 2) \), neither of which has area divisible by 3.
The square $(3, 2)$ is bad in the $5E (5 + 3k)$ case, i.e., $R(5, n)$ if $(3, 2)$ cannot be tiled. For if $(3, 2)$ were good, some tromino $T$ would have to cover the square $(3, 1)$. If $T$ lay above $(3, 2)$ the square $(1, 1)$ could not be reached, otherwise the square $(5, 1)$ could not be reached. Symmetrically, $(3, 4 + 3k)$ is also bad in this case.

De- cient Rectangle Theorem (compare [CJ 1]). An $m \times n$ de- cient rectangle, $2 \cdot m \cdot n, 3 \mid mn \mid 1$, has a tiling, regardless of the position of the missing square, if and only if (a) neither side has length 2 unless both of them do, and (b) $m \equiv 5$. Furthermore, in all the exceptional cases the only bad squares are those enumerated in the preceding discussion.

Proof. For this proof only, we change notation slightly and let $R(m, n)^i$ denote an $m \times n$ rectangle of deficiency $i$. The "outlier" $R(2, 2)^i$ is tiled with one tromino. First assume that $m$, $4, m \equiv 5$, and $3 \cdot m$. The method of proof is to proceed inductively after treating the cases $m = 4, 7, 8, 10, 11$ individually. If $m = 13$, then $m \equiv 6 > 6$ so that we may slice a full rectangle of height $6$ on either the top or the bottom of $R(m, n)^i$, i.e., $R(m, n)^i = R(m, 6)^i + R(6, n)$. Since the last term is tileable by the Chu-Johnsonbaugh Theorem, this first reduces the cases $m = 2 [13, 17]$ to the cases $m = 2 [7, 11]$, then the cases $m = 2 [19, 23]$ to the cases $m = 2 [13, 17]$, and so on.

If $m = 4$, write $R(4, 3k + 1)^i = (k + 1)R(4, 3) + R(4, 4)^i$. Apply the Chu-Johnsonbaugh Theorem to the first $k + 1$ terms. For the last term, observe that in [G], Golomb showed that all $2^k \times 2^k$ deficient squares can be tiled. (Its proof is an induction argument almost identical to the one used above to tile the $2^k \times 2^k$ dog- eared squares.) If $m = 7$, we may write $R(7, n)^i = R(3, n) + R(4, n)^i$ and thus reduce the $m = 7$ case to the $m = 4$ case when $n$ is even; while if $n$ is odd, $6$ divides $n \equiv 7$ and $R(7, n)^i = (\frac{m-n}{6}) R(7, 6) + R(7, 7)^i$ is tileable using the Chu-Johnsonbaugh Theorem and reference [CJ 1]. If $m = 10$, then $R(10, n)^i = R(7, n)^i + R(3, n)$ so that the Chu-Johnsonbaugh Theorem provides a reduction to the $m = 7$ case if $n$ is even, while $R(10, n)^i = R(10, n + 3)^i + R(10, 3)$ reduces the odd $n$ case to the even $n$ case. If $m = 8, R(8, n)^i = R(8, 8 + 3k)^i = kR(8, 3)^i + R(8, 8)^i$ is tileable by the Chu-Johnsonbaugh Theorem and reference [G]. Finally if $m = 11$, $n$ must be congruent to either 8 or 11 modulo 6. If $n = 8 + 6k, R(11, 8 + 6k)^i = kR(11, 6) + R(11, 8)^i$ with the $i$rst terms tileable by the Chu-Johnsonbaugh Theorem and the last term tiled by the $m = 8$ case since $R(11, 8)^i = R(8, 11)^i$, while if $n = 11 + 6k, R(11, 11 + 6k)^i = kR(11, 6) + R(11, 11)^i$; the $i$rst terms are tileable by the Chu-Johnsonbaugh Theorem and the tiling of the last term can be found in reference [CJ 1].

In view of the treatment of all the bad cases before the statement of this theorem, it remains only to analyze the exceptional good cases. Since 3 divides $mn \equiv 1$, if $m = 2$, we must have $n = 2 + 3k, k = 0, 1, \ldots$, while if $m = 5$, we must have $n = 5 + 3k, k = 0, 1, 2, \ldots$. Also notice that the $(m, n) = (2, 2)$ case is not an exception. We'll start with the $5E 5$ good cases. The tiling in Figure 6 above shows
that (1, 5) is good, while these two tileings show (3, 5) and (3, 3) to be good.

![Figure 7. Tiling deficient 5 × 5 rectangles](image)

Symmetry considerations show that the remaining six marked tiles are also good. Thus all nine marked tiles are good.

Next, if \((m, n) = (2.5 + 3k), k = 0, 1, \ldots\), we determine to be good all the squares of the form \((x, 3j + 1)\) or \((x, 3j + 2), j = 0, 1, \ldots, k + 1\), where \(x = 1\) or \(2\). In fact, we may write any of these as \((k + 1)R(2, 3) + R(2, 2)^i\), apply (0.1) to each of the \(.rst k + 1\) terms, and use one more tromino to cover \(R(2, 2)^i\).

It remains to treat the deficient rectangles \(R(5, 8 + 3k)^i\), where \(k\), 0 and the removed square is neither \((3, 2)\) nor \((3, 7 + 3k)\). Assume that all the cases \(R(5, 8)^i\) and \(R(5, 11)^i\) have been done and that any square removed from now on is not \((3, 2)\). Let the square \((i, j)\) be removed from \(R(5, 14)\). Symmetry allows the assumption \(j = 7\). If \((i, j) \notin (3, 7)\), then the decomposition of the resulting \(R(5, 14)^i\) into an \(R(5, 8)^i\) on the left and an \(R(5, 6)\) on the right allows a tiling, while \(R(5, 14)^i\) is tiled by decomposing it into an \(R(5, 6)\) on the left and an \(R(5, 8)^i\) on the right. The cases of \(R(5, n), n \geq 17\) will be treated inductively.

Symmetry allows us to consider only \(R(5, n)\) of the form \((j, n)\) where \(j = n/2 < n \notin 8\) and where all but 2 tiles of \(R(5, n)^i\) are good. Now decompose into \(R(5, n)\) on the left and \(R(5, 6)\) on the right. Since \(j \notin (n/6)\) the \(.rst\) term may be tiled, while the second is tiled with the Chu-Johnsonbaugh Theorem.

The cases \(R(5, 8)\) by symmetry we may assume \(i = 3\) and \(j = 4\). Since \((3, 2)\) is bad, we have 11 cases to show good. If \(i = 4\) and \(j \notin 2, 4, 6\) then \((i, j)\) is a good square of \(R(2, 8)^i\), so the decomposition of \(R(5, 8)^i\) into a full upper rectangle \(R(3, 8)\) and a lower \(R(2, 8)^i\) works in all six of these cases. There remain the \(ve \) cases \((i, j) = (3, 1), (5, 3), (4, 3), (3, 3), \) and \((3, 4)\). These are done in ad hoc fashion.
in Figure 8.

![Tiling Diagram](image)

Figure 8. Decent 5 \( \times \) 8 tilings

The cases \( R(5, 11) \). By symmetry we may assume \( i \leq 3 \) and \( j \leq 6 \). Since \((3, 2)\) is bad, we have 17 cases to show good. If \( i \) and \( j \) are both odd, \((i, j)\) is a good square of \( R(5, 5) \), so the decomposition of \( R(5, 11) \) into a left \( R(5, 5) \) and a full right \( R(5, 6) \) works for these 6 cases. The remaining 11 cases are done in ad hoc
fashion in Figure 9.

Figure 9. Deicient 5 £ 11 tilings

Results and questions about 2-deciency

The following proposition disallows the possibility of making the natural definition of deiciency of order \( k, k \geq 2 \) and then finding a direct extension of the Deicient Rectangle Theorem for higher deficiencies.

Proposition. No rectangle has the property that no matter which two 1 £ 1 squares are removed, the remaining shape of area \( mn \geq 2 \) can be tiled.

For if the squares (2,1) and (2,2) are removed, then the square (1,1) cannot be covered by a tromino.
Even though there will not be a direct analogue of the Deicient Rectangle Theorem, there is room for some interesting work to be done here. Here is a program for what to do about 2-deiciency. We extend the definition of good to 2-deiciency. A pair of squares is good if their removal from a \( m \times n \) rectangle leaves a figure which can be tiled.

**Problem.** Deal with the general case of 2-deiciency by finding all bad pairs of squares for all \( m \times n \) rectangles where \( mn \not\equiv 2 \mod 3 \). Slightly less generally, exactly when can such a rectangle be covered by one domino and \( (mn - 2)/3 \) trominoes?

On the negative side, as we pointed out in the proof of the Proposition, the pair \( f(2,1), (2,2)g \) is bad, that is, if square \( (2,1) \) and square \( (2,2) \) are removed, then no tromino can cover square \( (1,1) \). On the positive side, recall that in the application given after the proof of the Dog-eared Rectangle Theorem we pointed out that a tiling is always possible if the two removed squares are adjacent and in a corner of the rectangle. In other words, if \( mn \not\equiv 2 \mod 3 \), then the pair \( f(1,n), (2,n)g \) is good. Now consider the \( 5 \times 7 \) case. As in the analysis of the \( 5 \times 5 \) case for deicient rectangles done above, form a checkerboard-like pattern by marking each of the 12 squares that have both coordinates odd and assume that two of the 23 unmarked squares have been removed from \( R(5,7) \) to form \( R^m \). Then a proposed tiling of \( R^m \) must contain one tromino for each of the 12 marked squares, so that tiling must have area at least \( 12 \times 3 \times \frac{3}{2} = 36 \), which is absurd since the area of \( R^m \) is 33. This reasoning disqualifies 253 pairs. Similar reasoning identifies a large number of bad pairs for \( R(5,13), \ldots, R(5,7 + 6k), \ldots \).

**Acknowledgments.** Marshall Ash had productive discussions with Ayse Sahin and Roger Jones. Martin Gardner provided encouragement and some references. Elizabeth Breuer motivated the application given after the proof of the Dog-eared Rectangle Theorem. Jerrold Griggs and a referee provided helpful historical information. We thank Frank Farris and the referees for style-improving suggestions.
